Problem 1. Show that each of the following initial-value problems has a unique solution and find the solution. Can Theorem 5.4 be applied in each case?

a. $y' = t^{-2}(\sin 2t - 2ty), \quad 1 \leq t \leq 2, \quad y(1) = 2;$ and

b. $y' = -y + t\sqrt{y}, \quad 2 \leq t \leq 3, \quad y(2) = 2.$

Solution.

a. The domain of $f(t, y) = \frac{\sin 2t - 2ty}{t^2}$ is $D = [1, 2] \times \mathbb{R}$. It is clear that f is continuous on D . Fix a $t \in [1, 2]$. Then, for $y_1, y_2 \in \mathbb{R}$,

$$\begin{aligned} |f(t, y_1) - f(t, y_2)| &= \frac{2t|y_1 - y_2|}{t^2} \\ &\leq 2|y_1 - y_2|, \end{aligned}$$

which implies f satisfies a Lipschitz condition in the variable y on D with a Lipschitz constant 2.

By Theorem 5.4, the initial-value problem has a unique solution. Using calculus, we have

$$\begin{aligned} t^2 y' + 2ty &= \sin 2t \\ t^2 y &= -\frac{1}{2} \cos 2t + C \\ \xrightarrow{y(1)=2} y &= \frac{-\cos 2t + 4 + \cos 2}{2t^2}. \end{aligned}$$

b. We can find that it is a Bernoulli's equation in the form of

$$y' + (1) \cdot y = t \cdot y^{1/2}.$$

Hence, we can find the solution as follows:

$$\begin{aligned} y' + (1) \cdot y &= t \cdot y^{1/2} \\ y' y^{-1/2} + y^{1/2} &= t \\ (\text{Let } u = y^{1/2}) \quad 2u' + u &= t. \end{aligned}$$

It is clear that the homogeneous solution is $u_h = Ce^{-t/2}$. The non-homogeneous solution will be $u_n = -t + 2$. Hence, it has a unique solution; the general solution of the original equation is

$y_g = (Ce^{-t/2} - t + 2)^2$. By the assumption of the initial value, we have $y = (e\sqrt{2} \cdot e^{-t/2} - t + 2)^2$. Since it does not satisfies a Lipschitz condition on $D = [2, 3] \times \mathbb{R}$ (here $y \geq 0$), Theorem 5.4 cannot be applied in this case. \square

Problem 2. For each choice of $f(t, y)$ given in the following:

- i. Does f satisfy a Lipschitz condition on $D = \{(t, y) \mid 0 \leq t \leq 1, -\infty < y < \infty\}$?
- ii. Can Theorem 5.6 be used to show that the initial-value problem

$$y' = f(t, y), \quad 0 \leq t \leq 1, \quad y(0) = 1$$

is well-posed?

- a. $f(t, y) = e^{t-y}$; and
- b. $f(t, y) = \frac{1+y}{1+t}$.

Solution.

- a. Fix a $t \in [0, 1]$. Then, for $y_1, y_2 \in \mathbb{R}$ with $y_1 > y_2$,

$$\begin{aligned} |e^{t-y_1} - e^{t-y_2}| &\geq |e^{-y_1} - e^{-y_2}| \\ &\geq e^{-y_2} \end{aligned}$$

is unbounded, which implies that f does not satisfy a Lipschitz condition on D in the variable y .

We cannot use Theorem 5.6 here since f does not satisfy a Lipschitz condition.

- b. Fix a $t \in [0, 1]$. Then, for $y_1, y_2 \in \mathbb{R}$,

$$\left| \frac{1+y_1}{1+t} - \frac{1+y_2}{1+t} \right| \leq |y_1 - y_2|,$$

which implies f satisfies a Lipschitz condition in the variable y on D with Lipschitz constant 1.

Since f is continuous on D , by Theorem 5.6, the initial-value problem is well-posed. \square

Problem 3. Use Euler's method to approximate the solutions for each of the following initial-value problems.

a. $y' = \frac{2 - 2ty}{t^2 + 1}$, $0 \leq t \leq 1$, $y(0) = 1$ with $h = 0.1$; and

b. $y' = \frac{y^2}{1 + t}$, $1 \leq t \leq 2$, $y(1) = -\frac{1}{\ln 2}$ with $h = 0.1$.

Show that the actual solutions are indeed $y(t) = \frac{2t + 1}{t^2 + 1}$ and $y(t) = \frac{-1}{\ln(t + 1)}$, respectively. Plot the errors between your numerical solutions and the exact solutions. Draw your conclusion regarding to the order of error with respect to the time step dt .

Solution.

- a. We directly differentiate the function and see whether it is a solution. Let $y(t) = \frac{2t + 1}{t^2 + 1}$. It is clear that $y(0) = 1$, and we have

$$\begin{aligned} y'(t) &= \frac{2(t^2 + 1) - (2t + 1)(2t)}{(t^2 + 1)^2} \\ &= \frac{2}{t^2 + 1} - \frac{2t}{t^2 + 1} \frac{2t + 1}{t^2 + 1} \\ &= \frac{2 - 2ty}{t^2 + 1}. \end{aligned}$$

The graph of the approximated solution and the actual solution can be seen below. The graph of error can also be seen below.

- b. We directly differentiate the function and see whether it is a solution. Let $y(t) = \frac{-1}{\ln(t+1)}$. It is clear that $y(1) = -\frac{1}{\ln 2}$, and we have

$$\begin{aligned} y'(t) &= \frac{1/(t+1)}{(\ln(t+1))^2} \\ &= \frac{y^2}{1+t}. \end{aligned}$$

The graph of the approximated solution and the actual solution can be seen below. The graph of error can also be seen below.

The code for Problem 3

Problem 4. Given the initial-value problem

$$y' = -y + t + 1, \quad 0 \leq t \leq 5, \quad y(0) = 1$$

with exact solution $y(t) = e^{-t} + t$.

- Approximate $y(5)$ using Euler's method with $h = 0.2$, $h = 0.1$, and $h = 0.05$.
- Determine the optimal value of h to use in computing $y(5)$, assuming $\delta = 10^{-6}$ and that Eq. (5.14) is valid.

Solution.

- Using Euler's method with

$$\omega_{i+1} = \omega_i + h(-y + hi + 1), \quad i = 1, 2, \dots, \frac{5-0}{h}.$$

By Python, we have

$$y(5) \approx 5.003777893186297 \quad \text{when } h = 0.2;$$

$$y(5) \approx 5.005153775207321 \quad \text{when } h = 0.1;$$

$$y(5) \approx 5.005920529220334 \quad \text{when } h = 0.05;$$

- By assuming (5.14) is true and $\delta = 10^{-6}$, the minimal value of $E(h)$ occurs when

$$h = \sqrt{\frac{2 \cdot 10^{-6}}{\max_{t \in [0,5]} |e^{-t}|}} = \sqrt{2 \cdot 10^{-6}} \approx 1.4142135623731 \times 10^{-3}.$$

□

```

2.     y_0 = 1
3.     N = int((b - a) / h)
4.     for i in range(N):
5.         y_0 += h * f(a + h * i, y_0)
6.     return y_0
7.
8. def f_4(t, y):
9.     return -y + t + 1
10.
11. for h in [0.2, 0.1, 0.05]:
12.     print(f"With h = {h}, the approximation is {euler_method(f_4, h, 0, 5)}."
```

The code for Problem 4a

Problem 5. Use Taylor's method of order two to approximate the solutions for each of the following initial-value problems.

a. $y' = \frac{1+t}{1+y}$, $1 \leq t \leq 2$, $y(1) = 2$ with $h = 0.5$; and

b. $y' = -y + t\sqrt{y}$, $2 \leq t \leq 3$, $y(2) = 2$ with $h = 0.25$.

Solution.

a. By calculus,

$$\frac{d}{dt} \frac{1+t}{1+y} = \frac{1}{1+y} - \frac{(1+t)^2}{(1+y)^3}.$$

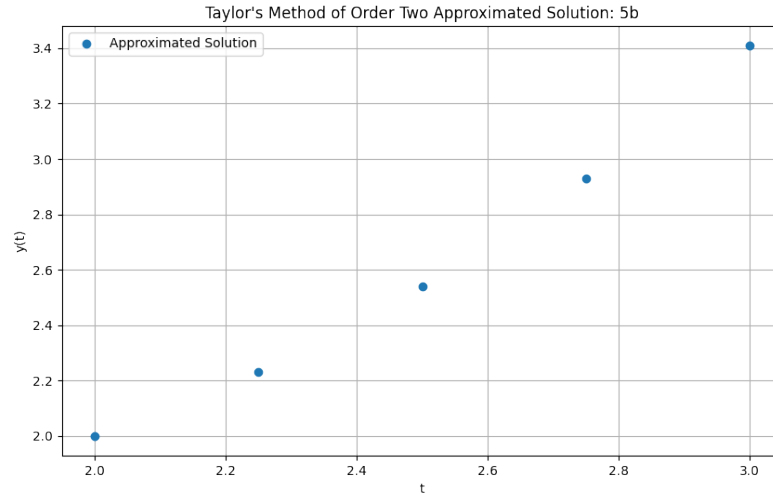

By Python, we have the following result:

b. By calculus,

$$\frac{d}{dt} (-y + t\sqrt{y}) = y + \sqrt{y} - \frac{3}{2}t\sqrt{y} + \frac{t^2}{2}.$$

By Python, we have the following result:

```

1. import math
2. import matplotlib.pyplot as plt
3.
4. def plot_array(x_axis, y_axis, title):
5.     plt.figure(figsize=(10, 6))
6.     plt.plot(x_axis, y_axis, 'o', label='Approximated Solution')
7.     plt.xlabel('t')
8.     plt.ylabel('y(t)')
9.     plt.title(title)
10.    plt.legend()
11.    plt.grid(True)
12.    plt.savefig(f"P{title[-2:]} .png", transparent=True)
13.
14. def taylor_method(n, f_family, alpha, a, b, h):
15.     N = int((b - a) / h)
16.     y_0 = alpha

48.
49. t_values_b, approx_soln_b = taylor_method(2, f_b_family, 2, 2, 3, 0.25)
50.
51. plot_array(t_values_b, approx_soln_b, "Taylor's Method of Order Two Approximated Solution: 5b")

```

The code for Problem 5

Problem 6. Given the initial-value problem

$$y' = \frac{2}{t}y + t^2e^t, \quad 1 \leq t \leq 2, \quad y(1) = 0$$

with exact solution $y(t) = t^2(e^t - e)$.

- a. Use Taylor's method of order two with $h = 0.1$ to approximate the solution, and compare it with the actual values of y .
- b. Use the answers generated in part (a) and linear interpolation to approximate y at the following values, and compare them to the actual values of y .
 - i. $y(1.04)$;
 - ii. $y(1.55)$; and
 - iii. $y(1.97)$.
- c. Use Taylor's method of order four with $h = 0.1$ to approximate the solution, and compare it with the actual values of y .
- d. Use the answers generated in part (c) and piecewise cubic Hermite interpolation to approximate y at the following values, and compare them to the actual values of y .
 - i. $y(1.04)$;
 - ii. $y(1.55)$; and
 - iii. $y(1.97)$.

Solution.

- a. By calculus,

$$\begin{aligned} \frac{d}{dt} \left(\frac{2}{t}y + t^2e^t \right) &= -\frac{2}{t^2}y + \frac{2}{t}y' + 2te^t + t^2e^t \\ &= \frac{2y}{t^2} + (4t + t^2)e^t. \end{aligned}$$

By Python, we have the following result:

b. By (a), we have the following table:

t	Approximation	Real Value
1	0	0
1.1	0.3397852286	0.3459198765
1.2	0.8521434493	0.8666425358
1.3	1.5817695052	1.6072150782
1.4	2.5809966497	2.6203595512
1.5	3.9109845593	3.9676662942

The code for Problem 6

Problem 7. Use the modified Euler method to approximate the solutions to each of the following initial-value problems, and compare the results to the actual values.

- a. $y' = \frac{y^2}{1+t}$, $1 \leq t \leq 2$, $y(1) = -\frac{1}{\ln 2}$ with $h = 0.1$; actual solution $y = \frac{-1}{\ln(t+1)}$; and
- b. $y' = \frac{y^2 + y}{t}$, $1 \leq t \leq 3$, $y(1) = -2$ with $h = 0.2$; actual solution $y(t) = \frac{2t}{1-2t}$.

Solution. By Python, we have the following results:

- a. The first graph is with approximated solution and the actual solution; the second graph is the error plot graph. In the error plot graph, I used lines to connect each pair of adjacent dots to increase visual clarity.

- b. The first graph is with approximated solution and the actual solution; the second graph is the error plot graph. In the error plot graph, I used lines to connect each pair of adjacent dots to increase visual clarity.

The code for Problem 10

Problem 11. The initial-value problem

$$y' = e^y, \quad 0 \leq t \leq 0.2, \quad y(0) = 1$$

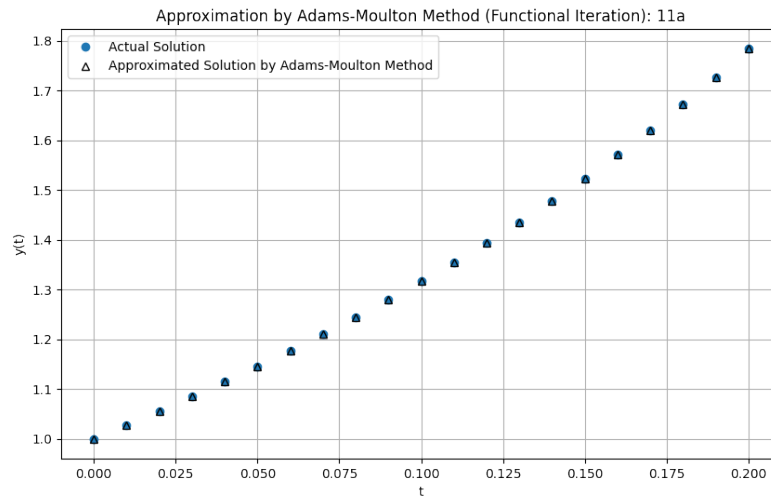

has solution $y(t) = 1 - \ln(1 - et)$. Applying the three-step Adams-Moulton method to this problem is equivalent to finding the fixed point ω_{i+1} of

$$g(\omega) = \omega_i + \frac{h}{24} (9e^\omega + 19e^{\omega_i} - 5e^{\omega_{i-1}} + e^{\omega_{i-2}}).$$

- With $h = 0.01$, obtain ω_{i+1} by functional iteration for $i = 2, \dots, 19$ using exact starting values ω_0, ω_1 , and ω_2 . At each step use ω_i to initially approximate ω_{i+1} .
- Will Newton's method speed the convergence over functional iteration?

Solution.

- I use fixed-point iteration with accuracy 10^{-8} for each ω_{i+1} , $i = 2, 3, \dots, 19$. The solution is approximated as follows:

- Since fix-point iteration converges linearly and Newton's method converges quadratically, Newton's method will speed the convergence over functional iteration. □

The code for Problem 11 a

Problem 12. Derive the Adams-Bashforth three-step method by the following method. Set

$$y(t_{i+1}) = y(t_i) + ah f(t_i, y(t_i)) + bh f(t_{i-1}, y(t_{i-1})) + ch f(t_{i-2}, y(t_{i-2})).$$

Expand $y(t_{i+1})$, $f(t_{i-2}, y(t_{i-2}))$, and $f(t_{i-1}, y(t_{i-1}))$ in Taylor series about $(t_i, y(t_i))$, and equate the coefficients of h , h^2 , and h^3 to obtain a , b , and c .

Solution. Since $y'(t) = f(t, y(t))$,

$$y(t_{i+1}) = y(t_i) + ah y'(t_i) + bh y'(t_{i-1}) + ch y'(t_{i-2}),$$

where

$$\begin{aligned} y(t_{i+1}) &= y(t_i + h) \\ &= y(t_i) + h y'(t_i) + \frac{h^2}{2} y''(t_i) + \frac{h^3}{6} y'''(t_i) + \cdots, \\ y'(t_{i-1}) &= y'(t_i - h) \\ &= y'(t_i) - h y''(t_i) + \frac{h^2}{2} y'''(t_i) - \cdots, \\ y'(t_{i-2}) &= y'(t_i - 2h) \\ &= y'(t_i) - 2h y''(t_i) + \frac{4h^2}{2} y'''(t_i) - \cdots. \end{aligned}$$

Hence, we have

$$\begin{aligned} h y'(t_i) &= ah y'(t_i) + bh y'(t_i) + ch y'(t_i) \\ \frac{h^2}{2} y''(t_i) &= -ah^2 y''(t_i) - 2ch y''(t_i) \\ \frac{h^3}{6} y'''(t_i) &= \frac{bh^3}{2} y'''(t_i) + \frac{4ch^3}{2} y'''(t_i), \end{aligned}$$

which yields $(a, b, c) = \left(\frac{23}{12}, -\frac{4}{3}, \frac{5}{12} \right)$. □

Problem 13. Use the Adams variable step-size predictor-corrector algorithm with $TOL = 10^{-4}$ to approximate the solutions to the following initial-value problems:

a. $y' = \sin t + e^{-t}$, $0 \leq t \leq 1$, $y(0) = 0$ with $hmax = 0.2$ and $hmin = 0.01$; and

b. $y' = -ty + \frac{4t}{y}$, $0 \leq t \leq 1$, $y(0) = 1$ with $hmax = 0.2$ and $hmin = 0.01$.

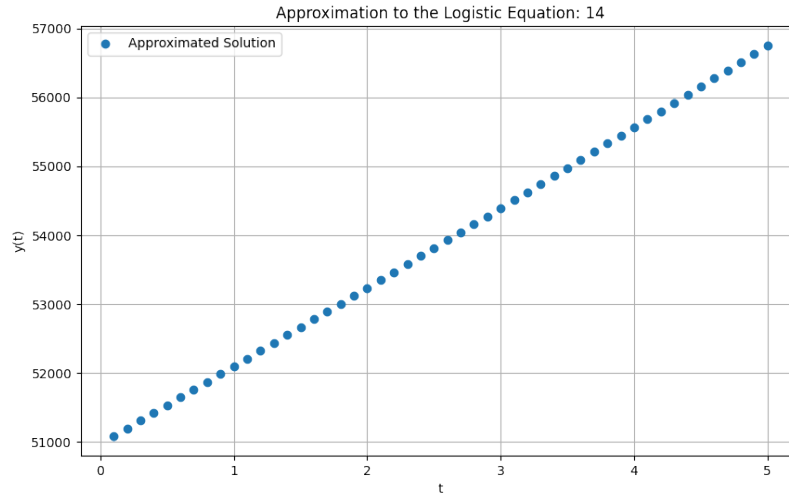

Solution.

Problem 14. Let $P(t)$ be the number of individuals in a population at time t , measured in years. If the average birth rate b is constant and the average death rate d is proportional to the size of the population (due to overcrowding), then the growth rate of the population is given by the logistic equation

$$\frac{dP}{dt}(t) = b P(t) - k(P(t))^2,$$

where $d = k P(t)$. Suppose $P(0) = 50976$, $b = 2.9 \times 10^{-2}$, and $k = 1.4 \times 10^{-7}$. Find the population after 5 years using the extrapolation method (based on the Euler method and the midpoint method) with times step $h = 0.1$. Justify the order of truncation error from your numerical answers.

Solution. Using the extrapolation method, by Python, the solution on $[0, 5]$ is approximated as follows:

Hence $y(5) = 56751.0367687$. Since $k = 3$ in the code, the order of truncation error is $\mathcal{O}(h^6)$. □

The code for Problem 14

Problem 15. Suppose the swinging pendulum described in the lead example of this chapter is 2 ft long and that $g = 32.17 \text{ ft/s}^2$. With $h = 0.1 \text{ s}$, compare the angle θ obtained for the following two initial-value problems at $t = 0, 1, 2$.^a

$$\frac{d^2\theta}{dt^2} + \frac{g}{L} \sin \theta = 0, \quad \theta(0) = \frac{\pi}{6}, \quad \theta'(0) = 0.$$

You shall use Adams fourth-order predictor-corrector algorithm to obtain your numerical answer.

^aI read this as “find values of $\theta(1)$ and $\theta(2)$ given $\theta(0) = \pi/6$.”

Solution.

Problem 16. Consider the differential equation

$$y' = f(t, y), \quad a \leq t \leq b, \quad y(a) = \alpha.$$

a. Show that

$$y'(t_i) = \frac{-3y(t_i) + 4y(t_{i+1}) - y(t_{i+2}))}{2h} + \frac{h^2}{3}y'''(\xi_i)$$

for some $\xi_i \in (t_i, t_{i+2})$.

b. Part (a) suggests the difference method

$$\omega_{i+2} = 4\omega_{i+1} - 3\omega_i - 2h f(t_i, \omega_i), \quad \text{for } i = 0, 1, 2, \dots, N-2.$$

Use this method to solve

$$y' = 1 - y, \quad 0 \leq t \leq 1, \quad y(0) = 0$$

with $h = 0.1$. Use the starting values $\omega_0 = 0$ and $\omega_1 = y(t_1) = 1 - e^{-0.1}$.

c. Repeat part (b) with $h = 0.01$ and $\omega_1 = 1 - e^{-0.01}$.

d. Analyze this method for consistency, stability, and convergence.

Solution.

a. We have

$$y(t_{i+1}) = y(t_i) + hy'(t_i) + \frac{h^2}{2}y''(t_i) + \frac{h^3}{6}y'''(t_i) \cdots$$

and

$$y(t_{i+2}) = y(t_i) + 2hy'(t_i) + \frac{4h^2}{2}y''(t_i) + \frac{8h^3}{6}y'''(t_i) + \cdots.$$

Hence,

$$4y(t_{i+1}) - y(t_{i+2}) = 4y(t_i) + 2hy'(t_i) + \frac{2h^2}{3}y'''(t_i) + \cdots,$$

which implies

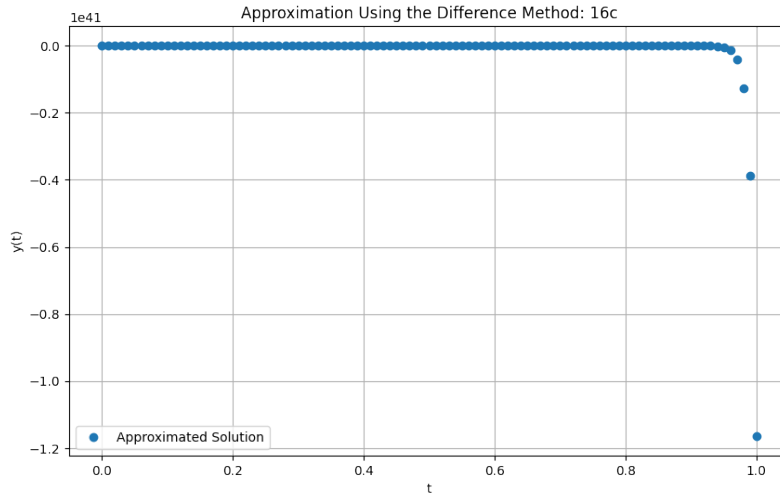

$$y'(t_i) = \frac{-3y(t_i) + 4y(t_{i+1}) - y(t_{i+2}))}{2h} + \frac{h^2}{3}y'''(\xi_i)$$

for some $\xi_i \in (t_i, t_{i+2})$.

b. By Python, the solution is approximated as follows:

c. By Python, the solution is approximated as follows:

d. The characteristic polynomial is

$$P(\lambda) = \lambda^2 - 4\lambda + 3,$$

which has roots 1, 3. Since one of them is with magnitude greater than one, the method does not satisfy the root condition. Thus, it is not stable and not convergent. From (a), we have

$$y'(t_i) = \frac{-3y(t_i) + 4y(t_{i+1}) - y(t_{i+2}))}{2h} + \frac{h^2}{3}y'''(\xi_i)$$

for some $\xi_i \in (t_i, t_{i+2})$. Hence, the truncation error is

$$\tau_i(h) = \frac{h^2}{3} y'''(\xi_1) = \frac{h^2}{3} f''(t, y(t)).$$

If the function $f''(t, y(t))$ is bounded on $[a, b]$, then

$$\lim_{h \rightarrow 0} \max_{1 \leq i \leq N} |\tau_i(h)| = 0,$$

which implies that the method is consistent; otherwise, the method is not consistent. □

Problem 17. Given the multistep method

$$\omega_{i+1} = -\frac{3}{2}\omega_i + 3\omega_{i-1} - \frac{1}{2}\omega_{i-2} + 3g f(t_i, \omega_i), \quad \text{for } i = 2, 3, \dots, N-1$$

with starting values ω_0 , ω_1 , and ω_2 :

- a. Find the local truncation error.
- b. Comment on consistency, stability, and convergence.

Solution.

Problem 18. Discuss consistency, stability, and convergence for the implicit trapezoidal method

$$\omega_{i+1} = \omega_i + \frac{h}{2} (f(t_{i+1}, \omega_{i+1}) + f(t_i, \omega_i)), \quad \text{for } i = 0, 1, 2, \dots, N-1$$

with $\omega_0 = \alpha$ applied to the differential equation

$$y' = f(t, y), \quad a \leq t \leq b, \quad y(a) = \alpha.$$

Solution.

Problem 19. Show that the fourth-order Runge-Kutta method,

$$k_1 = h f(t_i, \omega_i),$$

$$k_2 = h f(t_i + h/2, \omega_i + k_1/2),$$

$$k_3 = h f(t_i + h/2, \omega_i + k_2/2),$$

$$k_4 = h f(t_i + h, \omega_i + k_3),$$

$$\omega_{i+1} = \omega_i + \frac{1}{6} (k_1 + 2k_2 + 2k_3 + k_4)$$

when applied to the differential equation $y' = \lambda y$, can be written in the form

$$\omega_{i+1} = \left(1 + h\lambda + \frac{1}{2}(h\lambda)^2 + \frac{1}{6}(h\lambda)^3 + \frac{1}{24}(h\lambda)^4 \right) \omega_i.$$

Solution. We have $f(t, w) = \lambda w$. Hence, we have

$$k_1 = h\lambda\omega_i,$$

$$k_2 = h\lambda(\omega_i + k_1/2)$$

$$= h\lambda\omega_i + (h\lambda)^2\omega_i/2,$$

$$k_3 = h\lambda(\omega_i + k_2/2)$$

$$= h\lambda\omega_i + h\lambda(h\lambda\omega_i + (h\lambda)^2\omega_i/2)/2$$

$$= h\lambda\omega_i + (h\lambda)^2\omega_i/2 + (h\lambda)^3\omega_i/4,$$

$$k_4 = h\lambda(\omega_i + k_3)$$

$$= h\lambda\omega_i + (h\lambda)^2\omega_i + (h\lambda)^3\omega_i/2 + (h\lambda)^4\omega_i/4.$$

Therefore,

$$\begin{aligned}
\omega_{i+1} &= \omega_i + \frac{1}{6} (k_1 + 2k_2 + 2k_3 + k_4) \\
&= \omega_i + \frac{1}{6} [(h\lambda\omega_i) \\
&\quad + 2(h\lambda\omega_i + (h\lambda)^2\omega_i/2) \\
&\quad + 2(h\lambda\omega_i + (h\lambda)^2\omega_i/2 + (h\lambda)^3\omega_i/4) \\
&\quad + (h\lambda\omega_i + (h\lambda)^2\omega_i + (h\lambda)^3\omega_i/2 + (h\lambda)^4\omega_i/4)] \\
&= \omega_i + \frac{1}{6} \left(6 \cdot h\lambda\omega_i + 3 \cdot (h\lambda)^2\omega_i + 1 \cdot (h\lambda)^3\omega_i + \frac{1}{4} \cdot (h\lambda)^4\omega_i \right) \\
&= \omega_i \left(1 + h\lambda + \frac{1}{2}(h\lambda)^2 + \frac{1}{6}(h\lambda)^3 + \frac{1}{24}(h\lambda)^4 \right).
\end{aligned}$$
